Relating Superembeddings and Non-linear Realisations

J.M. Drummond

Department of Mathematics

King's College, London

Abstract

We discuss the relation between the superembedding method for deriving worldvolume actions for D-branes and the method of Partially Broken Global Supersymmetry based upon linear and non-linear realisations of SUSY. We give the explicit relation for the cases of space filling branes in 3 and 4 dimensions and show that the standard $\mathcal{F}$ -constraint of the superembedding method is the source of the required covariant non-linear constraints for the PBGS method.

1 Introduction

A superembedding is the embedding of one superspace inside another. The theory of such embeddings provides an excellent geometrical framework to describe the dynamics of superbranes. For a review of superembeddings see [1]. In fact all BPS branes are described by a superembedding satisfying a natural geometrical condition, namely that at all points on the brane the odd tangent space of the brane is a subspace of the odd tangent space of the superspacetime in which the brane lives.

This ‘embedding condition’ is often enough to describe the dynamics of the brane, that is it leads to a worldvolume multiplet for which an action can be written or sometimes it implies the equations of motion directly. For some cases, including some D-branes, the embedding condition leads to an under-constrained multiplet. In these cases an additional constraint is required to enable one to construct the brane action or equations of motion. This constraint is called the $\mathcal{F}$ -constraint. In the D-brane cases, one introduces an independent worldvolume 2-form modified field strength $\mathcal{F}$ satisfying $d\mathcal{F} = -H$ where H is the pullback of a closed target space (Neveu-Schwarz) 3-form. One then constrains $\mathcal{F}$ to have only purely bosonic components. This constraint can be justified by considering branes ending on other branes [2, 3, 4]. With this additional constraint one then has either an off-shell multiplet, in which case a brane action can be written, or an on-shell multiplet, i.e. satisfying the equations of motion.

In recent papers [5, 6] superembeddings with bosonic codimension zero were discussed in three, four and six dimensions. Although the number of bosonic dimensions is the same for the worldvolume and the target space these are genuine embeddings because the numbers of fermionic dimensions of these spaces are not the same. Specifically, the worldvolume has exactly half the number of the target space since these branes preserve half the supersymmetry of the background supergravity. The superembedding formalism was shown to be a powerful systematic method for the derivation of the dynamics of these space filling branes. In [5] Green-Schwarz and superfield actions were constructed for the three dimensional case. In [5, 6] the Green-Schwarz action in the four dimensional case was constructed and shown to be of the standard Born-Infeld type.

Since these branes preserve half the background supersymmetry, one can think of the superembedding of a space filling brane into flat space as the partial breaking of supersymmetry by one half (PBGS) [7]. The broken supersymmetry is said to be realised non-linearly. This idea has been applied to many cases [8, 9, 10, 11, 12, 13, 14]. In [8] the case of the space filling 3-brane was considered, and in [12] the membranes in three and four dimensions. Firstly one introduces a multiplet which transforms linearly under the full supersymmetry and then imposes constraints on it which relate its components to the Goldstone field of the broken supersymmetry. The superfield Lagrangian can be identified with one of the $N = 1$ superfield components of the original multiplet. For the space filling branes in three and four dimensions the multiplet which transforms linearly is the $N = 2$ Maxwell multiplet. This multiplet satisfies a deformation of the standard Maxwell constraints. In [15], an algorithm was given for deriving the constraints which relate the components of the $N = 2$ Maxwell multiplet to the Goldstone field in these cases. The constraints were found using the relationship between linear and non-linear realisations of supersymmetry [16], which was adapted to PBGS cases in [14, 17].

The relationship between non-linear realisations and superembeddings has been discussed before [18, 7, 19]. In [19] it was shown that the embedding condition of the superembedding formalism is equivalent to what is called the ‘inverse Higgs constraint’ of the non-linear realisation formalism. For the cases under consideration here the embedding condition can be imposed without loss of generality and we focus on the relationship of the $\mathcal{F}$ -constraint to the non-linear realisations framework. In this paper we explicitly show the equivalence between superembeddings and linear and non-linear realisations of PBGS for the cases of the space filling branes in three and four dimensions. We introduce a target space 2-form $\underline{F}$ for the $N = 2$ Maxwell multiplet and we write the deformation of the $N = 2$ Maxwell constraints as the modified Bianchi identity $d\underline{F} = -\underline{H}$. Pulling this equation back to the worldvolume, we obtain the worldvolume Bianchi identity for the two form $\mathcal{F}$ introduced in the superembedding formalism. We show that the non-linear constraints on the Maxwell fields imposed in the PBGS method are exactly the standard $\mathcal{F}$ -constraint. This equivalence allows us to show that the superfield actions defined by the superembedding method are the same as those invariants constructed using non-linear realisations of supersymmetry.

We begin by reviewing very briefly the procedure of embedding space filling branes into three and four dimensional flat superspaces and describing the method for the construction of brane actions. We then go on to show the equivalence with the linear and non-linear realisations method in the three dimensional case and then the four dimensional case. In section 3 we show the equivalence of the constraints of the two methods. In section 4 we show the equivalence of the actions defined by these methods.

2 Superembedding Method

We consider a superembedding $f : M \rightarrow \underline{M}$. Our index conventions are as follows; coordinate indices are taken from the middle of the alphabet with capitals for all, Latin for bosonic and Greek for fermionic, $M = (m, \mu)$, tangent space indices are taken in a similar fashion from the beginning of the alphabet so that $A = (a, \alpha)$. The distinguished tangent space bases are related to coordinate bases by means of the supervielbein, E_M^A , and its inverse E_A^M . Coordinates are denoted $z^M = (x^m, \theta^\mu)$. We use exactly the same notation for the target space but with all of the indices underlined. Target space forms are written with an underline, e.g. $\underline{H}$. Their pullbacks are written without an underline, $f^*\underline{H} = H$.

The embedding matrix is the derivative of f referred to the preferred tangent frames, thus

$$E_A^{\underline{A}} = E_A^M \partial_M z^{\underline{M}} E_{\underline{M}}^{\underline{A}} \quad (1)$$

This tells us how to pull back target space forms onto the worldvolume,

$$f^* E^{\underline{A}} = E^A E_A^{\underline{A}}. \quad (2)$$

The basic embedding condition is

$$E_\alpha^{\underline{a}} = 0. \quad (3)$$

This condition in general gives constraints on the superfields describing the worldvolume theory. For codimension zero however it can be enforced without loss of generality as discussed in [5].

The worldvolume multiplet is described by the transverse target space coordinates considered as superfields on the worldvolume. For codimension zero we embed an $N = 1$ superspace into an $N = 2$ superspace of the same bosonic dimension. Thus, in the absence of further constraints, an unconstrained spinor superfield describes our worldvolume multiplet.

2.1 Space Filling Branes

We shall give a brief review of how the superembedding approach is applied to the case of the space filling branes in flat three and four dimensional spacetime [5]. Our bosonic indices are the same for worldvolume and target space since we are considering space filling branes. Our fermionic target space indices are written $\underline{\alpha} = \alpha i$ where $i = 1, 2$ since we embed an $N = 1$ superspace into an $N = 2$ superspace. In 3 dimensions α is a real, two-component Majorana spinor index. In 4 dimensions α is a complex, two-component Weyl spinor index. The internal index i is an $SO(2)$ index for the 3 dimensional case and a $U(2)$ index for the 4 dimensional case.

Supergeometry

Firstly we specify the form of the worldvolume derivatives in terms of target space derivatives. As discussed in [5] we can parametrize the odd-odd part of the embedding matrix $E_{\alpha}^{\underline{\alpha}}$ as follows

$$E_{\alpha} = E_{\alpha 1} + h_{\alpha}^{\beta} E_{\beta 2} \quad (4)$$

i.e.

$$E_{\alpha}^{\beta 1} = \delta_{\alpha}^{\beta} \quad \text{and} \quad E_{\alpha}^{\beta 2} = h_{\alpha}^{\beta} \quad (5)$$

The worldvolume torsion can now be calculated by pulling back the standard flat target space torsion. As discussed in [5], for the codimension zero cases it is not necessary to introduce a worldvolume connection. Thus the torsion tells us the algebra of derivatives on the worldvolume. Writing our worldvolume tangent vectors E_A as $\mathcal{D}_A = E_A^M \partial_M$ we have

$$[\mathcal{D}_A, \mathcal{D}_B] = -T_{AB}^C \mathcal{D}_C. \quad (6)$$

This algebra is the same as that introduced in [8, 15] as the algebra one ends up with by imposing that the second supersymmetry in the $N = 2$ Poincaré superalgebra is realised non-linearly. A similar algebra is obtained in the case of the D-9 brane [20].

To describe the worldvolume multiplet, one introduces a worldvolume 2-form $\mathcal{F}$ (the modified field strength). This is constrained to satisfy the Bianchi identity,

$$d\mathcal{F} = -H \quad (7)$$

where H is the pullback onto the worldvolume of the constant, closed target space Neveu-Schwarz 3-form, $\underline{H}$. To get the required worldvolume $N = 1$ Maxwell multiplet one imposes the standard $\mathcal{F}$ -constraint $\mathcal{F}_{\alpha\beta} = \mathcal{F}_{ab} = 0$. The constraint $\mathcal{F}_{\alpha\beta} = 0$ tells us that we have an $N = 1$ Maxwell multiplet on the brane as well as the Goldstone fermion of the embedding. Then the constraint

$\mathcal{F}_{ab} = 0$ eliminates one of these spinor superfields in terms of the other. This leaves us with just the degrees of freedom associated with the Goldstone field. The Bianchi identity then gives a formula for $\mathcal{F}_{ab}$ in terms of the degrees of freedom of the embedding.

Green-Schwarz Action

To obtain the Green-Schwarz action for the brane we start with the Wess Zumino term in the D-brane Lagrangian [21]. We construct a $D + 1$ form $W_{D+1} = G_{D+1} + G_{D-1}\mathcal{F}$, where the G forms are pullbacks of constant super-invariant target space RR field strengths. This form can be written explicitly as $W_{D+1} = dZ_D$ where $Z_D = C_D + C_{D-2}\mathcal{F}$ and the C forms are the pullbacks of the non-invariant target space RR potentials.

Since W_{D+1} is a form of degree one higher than the body of the worldvolume the fact that it is closed implies it is also exact and so we can also write $W_{D+1} = dK_D$ for some K_D . The Lagrangian form is

$$L_D = K_D - Z_D \quad (8)$$

and is closed by construction. Finally the Green-Schwarz action is defined by

$$S_{GS} = \int d^D x \epsilon^{m_1 \dots m_D} L_{m_1 \dots m_D}(x, \theta = 0) \quad (9)$$

where the integration is taken over the bosonic worldvolume M_o .

Superfield Lagrangian and Static Gauge

To construct the superfield action [5] one has to make a choice of gauge. We choose the static gauge, defined by identifying the coordinates of the brane with some of the coordinates of the target space thus

$$x^{\underline{a}} = x^a \quad (10)$$

$$\theta^{\alpha 1} = \theta^\alpha \quad (11)$$

$$\theta^{\alpha 2} = \Lambda^\alpha(x, \theta). \quad (12)$$

From the definition of the embedding matrix we can see that our choice of coordinates implies that the field h_α^β which we introduced in (4) is the worldvolume covariant derivative of the transverse fermion field Λ ,

$$h_\alpha^\beta = \mathcal{D}_\alpha \Lambda^\beta. \quad (13)$$

With this choice of gauge, the embedding condition $E_\alpha^{\underline{a}} = 0$ implies the following for the worldvolume derivatives

$$\mathcal{D}_\alpha = D_\alpha + \psi_\alpha^a \partial_a \quad (14)$$

$$\mathcal{D}_a = B_a^b \partial_b \quad (15)$$

$$\text{where } \psi_\alpha^a \sim \frac{i}{2} D_\alpha \Lambda \Gamma^b \Lambda B_b^a \quad (16)$$

$$B_a^b \sim (\delta_b^a - \frac{i}{2} \partial_b \Lambda \Gamma^a \Lambda)^{-1}. \quad (17)$$

The precise forms of the quantities ψ and B depend on which dimension one considers.

Given these derivatives, the one-form bases on the brane are

$$E^\alpha = e^\alpha \quad (18)$$

$$E^a = (e^b - e^\beta \psi_\beta{}^b)(B^{-1})_b{}^a, \quad (19)$$

where e^a and e^α denote the standard one-form bases of flat superspace

$$e^\alpha = d\theta^\alpha \quad (20)$$

$$e^a = dx^a - \frac{i}{2} d\theta^\alpha (\Gamma^a)_{\alpha\beta} \theta^\beta. \quad (21)$$

These formulae allow one to convert form components from the basis induced by the embedding to the flat basis.

To construct the superfield Lagrangian one considers the components of the Lagrangian form in the flat basis e^A , denoted $l_{ABC\dots}$. Generically one finds that the component $l_{\alpha\beta c\dots}$ contains a term which can be identified with the superfield Lagrangian. In three dimensions this is a real superfield to be integrated over the whole worldvolume superspace and in four dimensions it is a chiral superfield to be integrated over half-superspace.

We now go on to describe the details of the superembedding for the space filling 2 and 3 branes.

2.2 D=3

Supergeometry

In three dimensions the embedding is described by

$$\mathcal{D}_\alpha = D_{\alpha 1} + h_\alpha{}^\beta D_{\beta 2} \quad \text{where} \quad h_{\alpha\beta} = k\epsilon_{\alpha\beta} + h_a(\gamma^a)_{\alpha\beta} \quad (22)$$

for k real.

The closed 3-form $\underline{H}$ has non-zero components

$$H_{\alpha i \beta j c} = -i(\gamma_c)_{\alpha\beta}(\tau_1)_{ij}, \quad (23)$$

where τ_1 is the first Pauli matrix.

Pulling this back to the worldvolume and solving $d\mathcal{F} = -H$ with the standard $\mathcal{F}$ -constraint we find that $k = 0$ and

$$\mathcal{F}_{ab} = \frac{2}{1 + h^2} \epsilon_{abc} h^c. \quad (24)$$

Action

The Wess-Zumino form is given by $W_4 = G_4 + G_2\mathcal{F}$ where the G forms are pullbacks of the target space RR field strengths whose non-zero components are

$$G_{\alpha i \beta j} = -i\epsilon_{\alpha\beta}\epsilon_{ij} \quad (25)$$

$$G_{\alpha i \beta j c d} = -i(\gamma_{cd})_{\alpha\beta}(\tau_3)_{ij}. \quad (26)$$

They satisfy the Bianchi identities

$$\underline{G}_2 = d\underline{C}_1, \quad (27)$$

$$\underline{G}_4 = d\underline{C}_3 - \underline{C}_1 \underline{H}_3. \quad (28)$$

These equations can be solved for the target space potentials $\underline{C}_1, \underline{C}_3$ so that their components are only functions of θ_2 . One can then pull them back to the worldvolume and calculate the components of the form $Z_3 = C_3 + C_1 \mathcal{F}$. Doing this one finds in static gauge

$$Z_{abc} = \epsilon_{abc} Z \quad \text{where} \quad Z = 1 + i\partial_a \Lambda \gamma^a \Lambda + \frac{1}{2} \Lambda^2 \partial_a \Lambda^\alpha \partial^a \Lambda_\alpha. \quad (29)$$

To complete the Green-Schwarz action we need the kinetic term. Since W_4 is exact we solve $W_4 = dK_3$. The only non-vanishing component of K_3 is the totally even one $K_{abc} = \epsilon_{abc} K$. One finds

$$K = \frac{1 - h^2}{1 + h^2} \quad (30)$$

which, given the relation (24) between h_a and $\mathcal{F}_{ab}$ can be shown to be of the standard Born-Infeld form.

$$K = \sqrt{\det(\eta_{ab} + \mathcal{F}_{ab})} \quad (31)$$

The Lagrangian form L_3 has the top component $L_{abc} = \epsilon_{abc} L$ where $L = K - Z$. One converts into the coordinate basis using the worldvolume supervielbein E_m^a to obtain the Green-Schwarz Lagrangian

$$L_{GS} = \det(E) L. \quad (32)$$

The superfield Lagrangian for $D = 3$ is found in the $\alpha\beta c$ component of L in the flat basis [5] :

$$L_o \propto (\gamma^c)^{\alpha\beta} l_{\alpha\beta c} \quad \text{i.e.} \quad L_{GS} = D^2 L_o. \quad (33)$$

2.3 D=4

Supergeometry

The embedding for $D = 4$ is specified by

$$\mathcal{D}_\alpha = D_{\alpha 1} + h_\alpha^\beta D_{\beta 2} \quad \text{where} \quad h_{\alpha\beta} = k\epsilon_{\alpha\beta} + h_{(\alpha\beta)} \quad (34)$$

for k complex.

The closed 3-form $\underline{H}$ has non-zero components

$$H_{\alpha i \beta c}^j = -i(\sigma_c)_{\alpha\beta} (\tau_1)_i^j. \quad (35)$$

We now pull $\underline{H}$ back to the worldvolume and solve $d\mathcal{F} = -H$ with the standard $\mathcal{F}$ -constraint. Firstly we find that the embedding preserves chirality, i.e. that $h_{\dot{\alpha}}^\beta = 0$, which in static gauge

says $\bar{\mathcal{D}}_{\dot{\alpha}}\Lambda^{\beta} = 0$. We say that the Goldstone field Λ is covariantly chiral. We also get an expression for $\mathcal{F}_{ab}$ in terms of h_{α}^{β} . Defining the variable $s^2 = -\frac{1}{2}h_{(\alpha\beta)}h^{\alpha\beta}$, we find that

$$\mathcal{F}_{ab} = (\sigma_{ab})_{\alpha\beta}M^{\alpha\beta} - (\tilde{\sigma}_{ab})_{\dot{\alpha}\dot{\beta}}\bar{M}^{\dot{\alpha}\dot{\beta}} \quad (36)$$

$$\text{where } M_{\alpha\beta} = h_{(\alpha\beta)}X(h) \quad (37)$$

$$\text{and } X(h) = \frac{-(1+k\bar{k})+s^2}{(1+k\bar{k})^2-s^2\bar{s}^2}. \quad (38)$$

We also find a constraint which removes one degree of freedom from the complex scalar k , namely

$$k + \bar{k} + k(\bar{k}^2 - \bar{s}^2) + \bar{k}(k^2 - s^2) = 0. \quad (39)$$

This is the full form of the non-linear reality constraint on the covariantly chiral Goldstone field Λ if we make the identification $h_{\alpha}^{\beta} = \mathcal{D}_{\alpha}\Lambda^{\beta}$. This constraint was first written down to third order in Λ in [8]. The remaining degree of freedom in k is the auxiliary field of the $D = 4$, $N = 1$ Maxwell multiplet.

Action

The Wess-Zumino form is given by $W_5 = G_5 + G_3\mathcal{F}$ where the G forms are pullbacks of the target space RR field strengths whose non-zero components are

$$G_{\alpha i \dot{\beta} c}^j = -i(\sigma)_{\alpha\dot{\beta}}(\tau_2)_i^j \quad (40)$$

$$G_{\alpha i \dot{\beta} cde}^j = -i\epsilon_{cdef}(\sigma^f)_{\alpha\dot{\beta}}(\tau_3)_i^j. \quad (41)$$

They satisfy the Bianchi identities

$$\underline{G}_3 = d\underline{C}_3, \quad (42)$$

$$\underline{G}_5 = d\underline{C}_4 - \underline{C}_2 H_3. \quad (43)$$

These equations can be solved for the target space potentials $\underline{C}_2, \underline{C}_4$ so that their components are only functions of $\theta_2, \bar{\theta}_2$. One can then pull them back to the worldvolume and calculate the components of the form $Z_4 = C_4 + C_2\mathcal{F}$. Doing this one finds

$$Z_{abcd} = \epsilon_{abcd}Z \quad (44)$$

where

$$Z = -1 + (iB_a{}^e\partial_e\Lambda\sigma^a\bar{\Lambda} + \text{c.c.}) - \frac{1}{2}(B_b{}^f B_a{}^e\partial_f\Lambda\sigma^{ab}\partial_e\Lambda\bar{\Lambda}^2 + \text{c.c.}). \quad (45)$$

The matrix $B_a{}^b$ is given by

$$B_a{}^b = (\delta_a^b + \frac{i}{2}\partial_a\sigma^b\bar{\Lambda} + \frac{i}{2}\partial_a\bar{\Lambda}\sigma^b\Lambda)^{-1}. \quad (46)$$

To complete the Green-Schwarz action we need the kinetic term. Since W_5 is exact we solve $W_5 = dK_4$. The only non-vanishing component of K_4 is totally even one $K_{abcd} = \epsilon_{abcd}K$. One finds

$$K = 1 + X(h) + \bar{X}(h) \quad (47)$$

The Lagrangian form L_4 has the top component $L_{abcd} = \epsilon_{abcd}L$ where $L = K - Z$. One converts into the coordinate basis using the worldvolume supervielbein $E_m{}^a$ to obtain the Green-Schwarz Lagrangian

$$L_{GS} = \det(E)L. \quad (48)$$

In four dimensions one can construct a chiral Lagrangian to be integrated over half-superspace. This chiral superfield Lagrangian is found in the $\dot{\alpha}\dot{\beta}cd$ component of L in the flat basis [5],

$$L_o \propto (\tilde{\sigma}^{cd})^{\dot{\alpha}\dot{\beta}} l_{\dot{\alpha}\dot{\beta}cd} \quad \text{i.e.} \quad L_{GS} = D^2 L_o + \bar{D}^2 \bar{L}_o. \quad (49)$$

3 Equivalence with non-linear realisations

In this section we shall show the explicit relationship of the generic superembedding approach to the PBGS method using linear and non-linear realisations of SUSY [15] for the case of the space filling D-branes in 3 and 4 dimensions. Firstly we shall discuss the general approach to showing this equivalence and then we shall go on to give the specific formulae for the two cases under discussion. We shall show in particular that the standard $\mathcal{F}$ -constraint is equivalent to the non-linear constraints imposed in [8, 12].

Our method will be to construct the 2-form $\mathcal{F}$ of the superembedding method in the following way. Firstly we introduce the $N = 2$ Maxwell multiplet via an independent target space 2-form $\underline{F}$. We constrain $\underline{F}$ to solve the modified target space Bianchi identity

$$d\underline{F} = -\underline{H} \quad (50)$$

with the standard constraint which gives the $N = 2$ Maxwell multiplet, i.e. that the lowest component of $\underline{F}$ is written

$$F_{\alpha i \beta j} \propto \epsilon_{\alpha\beta} \epsilon_{ij} W \quad (51)$$

where W is an $N = 2$ scalar superfield that is real in 3 dimensions and chiral in 4 dimensions.

In both three and four dimensions the Bianchi identity (50) imposes modified constraints on the $N = 2$ Maxwell multiplet. These constraints are precisely the deformations of the Maxwell constraints imposed in [8, 12, 15].

We then pull back the 2-form $\underline{F}$ onto the worldvolume of the brane identifying $f^*\underline{F}$ with $\mathcal{F}$. By (50) we are guaranteed that $\mathcal{F}$ defined this way satisfies the correct worldvolume Bianchi identity (7). The components of $\mathcal{F}$ are given by

$$\mathcal{F}_{AB} = (-1)^{A.(B+\underline{B})} E_B{}^{\underline{B}} E_A{}^{\underline{A}} \underline{F}_{\underline{A}\underline{B}} \big|_{\theta_2=\Lambda}. \quad (52)$$

We can eliminate any target space derivatives D_1 in favour of D_2 and worldvolume derivatives $\mathcal{D}$ since we have specified the embedding to be described by (4),

$$\mathcal{D}_\alpha = D_{\alpha 1} + h_\alpha{}^\beta D_{\beta 2}. \quad (53)$$

Having evaluated the components of $\mathcal{F}$ in terms of W , $D_2 W$ and $D_2^2 W$, we then impose the standard $\mathcal{F}$ -constraint $\mathcal{F}_{\alpha\beta} = \mathcal{F}_{ab} = 0$.

These constraints imply

$$W|_{\theta_2=\Lambda} = 0 \quad (54)$$

$$D_{\alpha 2} W|_{\theta_2=\Lambda} = 0. \quad (55)$$

If we now expand the superfield W in θ_2 we get generically

$$W = \phi + \theta_2^\alpha W_\alpha + \dots \quad (56)$$

We can see explicitly that the $\mathcal{F}$ -constraint implies some non-linear constraints on the component fields ϕ and W_α . These constraints are those postulated in the non-linear realisations framework in [8, 12] and later derived from an algorithmic procedure in [15].

We then go on to show that $\mathcal{F}_{ab}$ defined this way is identical to the one defined via the superembedding method described earlier.

3.1 D=3

We now show the explicit relation between the superembedding method and the method of using linear and non-linear realisations of PBGS for the three dimensional case. The components of $\underline{F}$ given by (50, 51) are

$$F_{\alpha i \beta j} = i\epsilon_{\alpha\beta}\epsilon_{ij}W \quad (57)$$

$$F_{\alpha i b} = \epsilon_{ij}(\gamma_b)_{\alpha\beta}D^{\beta j}W \quad (58)$$

$$F_{ab} = -i\epsilon_{abc}(\gamma^c)^{\alpha\beta}D_{\alpha 1}D_{\beta 2}W \quad (59)$$

where W is a real $N = 2$ scalar superfield satisfying the deformed Maxwell constraints of [12, 15]

$$(D_{\alpha 1}D_1^\alpha - D_{\alpha 2}D_2^\alpha)W = -2i \quad (60)$$

$$D_{\alpha 1}D_2^\alpha W = 0. \quad (61)$$

If we expand W in terms of θ_2 these constraints imply

$$W = \phi + i\theta_2^\alpha W_\alpha - i\theta_2^2(1 - iD_1^2\phi). \quad (62)$$

Next pull back the target space 2-form $\underline{F}$ onto the worldvolume defining $f^*\underline{F} = \mathcal{F}$.

The components of $\mathcal{F}$ are

$$\mathcal{F}_{\alpha\beta} = -2ih_{(\alpha\beta)}W \quad (63)$$

$$\mathcal{F}_{\alpha b} = (\gamma_b)_{\alpha\beta}D_2^\beta W + h_\alpha{}^\gamma(\gamma_b)_{\gamma\beta}(\mathcal{D}^\beta W - h^{\beta\delta}D_{\delta 2})W + i\mathcal{D}_b\Lambda^\alpha W \quad (64)$$

$$\mathcal{F}_{ab} = -i\epsilon_{abc}(\gamma^c)^{\alpha\beta}(\mathcal{D}_\alpha D_{\beta 2}W - h_\alpha{}^\gamma D_{\gamma 2}D_{\beta 2}W) - 2\left(\mathcal{D}_{[a}\Lambda^\alpha(\gamma_{b]})_{\alpha\beta}(\mathcal{D}^\delta W - h^{\delta\epsilon}D_{\epsilon 2}W)\right) \quad (65)$$

where all terms are evaluated at $\theta_2 = \Lambda$. We have written the derivatives $D_{\alpha 1}$ in the above expression in terms of $D_{\alpha 2}$ and worldvolume derivatives $\mathcal{D}_\alpha$.

We next impose the standard $\mathcal{F}$ -constraint on this object, i.e. we set $\mathcal{F}_{\alpha\beta} = \mathcal{F}_{ab} = 0$.

In terms of ϕ and W_α these constraints are precisely those of the PBGS method [12, 15]

$$\phi + i\Lambda^\alpha W_\alpha - i\Lambda^2(1 - iD^2\phi) = 0 \quad (66)$$

$$iW_\alpha + i\Lambda_\alpha(1 - iD^2\phi) + \frac{i}{2}\Lambda^\beta\partial_{\alpha\beta}\phi - \frac{1}{2}\Lambda^2\partial_{\alpha\beta}W^\beta = 0. \quad (67)$$

These give the relations

$$\phi = -i\Lambda^2(1 - iD^2\phi) \quad (68)$$

$$W_\alpha = -\Lambda_\alpha(1 - iD^2\phi). \quad (69)$$

We can solve (68) to get

$$\phi = \frac{-i\Lambda^2}{1 + D^2\Lambda^2}. \quad (70)$$

We can now use our relations for ϕ and W_α to check the expression for $\mathcal{F}_{ab}$. Using the relations (54,55,53) we can see that

$$\mathcal{F}_{ab} = i\epsilon_{abc}(\gamma^c)^{\alpha\beta}h_\alpha{}^\gamma D_{\gamma 2}D_{\beta 2}W\Big|_{\theta_2=\Lambda}. \quad (71)$$

We know from the $\mathcal{F}$ -constraint (54,55) that on the brane we can replace the modified Maxwell constraint(60) with

$$D_{\alpha 2}D_2^\alpha W = \frac{2i}{1 + h^2}. \quad (72)$$

Substituting this into (71) we do indeed find the same expression for $\mathcal{F}_{ab}$ as we had from the superembedding approach (24).

This is as expected since it is easy to see that $\mathcal{F}$ has to be unique. Consider $\mathcal{F}$ and $\mathcal{F}'$ satisfying

$$d\mathcal{F} = d\mathcal{F}' = -H \quad (73)$$

and both satisfying the standard $\mathcal{F}$ -constraint $\mathcal{F}_{\alpha\beta} = \mathcal{F}_{ab} = 0$. Then $P = \mathcal{F} - \mathcal{F}'$ satisfies

$$dP = 0 \quad (74)$$

and P_{ab} is the only non-zero component of P . The $\alpha\beta c$ component of (74) then implies

$$T_{\alpha\beta}{}^c P_{cd} = 0 \quad \text{i.e.} \quad P = 0. \quad (75)$$

Thus $\mathcal{F}$ defined by $d\mathcal{F} = -H$ and the standard $\mathcal{F}$ -constraint is unique.

3.2 D=4

We proceed in the same manner for four dimensions. The components of $\underline{F}$ given by (50,51) are

$$F_{\alpha i \beta j} = \epsilon_{\alpha\beta}\epsilon_{ij}\bar{W} \quad (76)$$

$$F_{\alpha i \beta}{}^j = 0 \quad (77)$$

$$F_{\alpha i b} = i\epsilon_{ij}(\sigma_b)_{\alpha\dot{\alpha}}\bar{D}^{\dot{\alpha}j}\bar{W} \quad (78)$$

$$F_{ab} = -\frac{1}{2}((\sigma_{ab})^{\alpha\beta}D_{\alpha i}D_{\beta j}W\epsilon^{ij} + (\tilde{\sigma}_{ab})^{\dot{\alpha}\dot{\beta}}\bar{D}_{\dot{\alpha}}^i\bar{D}_{\dot{\beta}}^j\bar{W}\epsilon_{ij}) \quad (79)$$

where W is a chiral $N = 2$ scalar superfield satisfying the deformed Maxwell constraints of [8, 15]

$$D_{\alpha 2} D_2^\alpha W + \bar{D}_\alpha^1 D^{\dot{\alpha} 1} \bar{W} = -2 \quad (80)$$

$$D_{\alpha 1} D_2^\alpha W - \bar{D}_\alpha^1 \bar{D}^{\dot{\alpha} 2} \bar{W} = 0 \quad (81)$$

$$\bar{D}_\alpha^i W = 0. \quad (82)$$

If we expand W in terms of θ_2 these constraints imply

$$W = \phi + \theta_2^\alpha W_\alpha + \theta_2^2 (1 - \bar{D}_1^2 \bar{\phi}) - \frac{i}{2} \theta_2^\alpha \bar{\theta}_2^{\dot{\alpha}} \partial_{\alpha \dot{\alpha}} \phi + \frac{i}{2} \theta_2^2 \bar{\theta}_2^{\dot{\alpha}} \partial_{\alpha \dot{\alpha}} W^\alpha - \frac{1}{8} \theta_2^2 \bar{\theta}_2^2 \square \phi \quad (83)$$

where ϕ and W_α are $N = 1$ superfields which are chiral in the θ_1 direction.

Next pull back the target space 2-form $\underline{F}$ onto the worldvolume defining $f^* \underline{F} = \mathcal{F}$. The components of $\mathcal{F}$ are

$$\mathcal{F}_{\alpha\beta} = -2h_{(\alpha\beta)} \bar{W} \quad (84)$$

$$\mathcal{F}_{\alpha\dot{\beta}} = 0 \quad (85)$$

$$\mathcal{F}_{ab} = i(\sigma_b)_{\alpha\dot{\alpha}} \bar{D}^{\dot{\alpha} 2} \bar{W} - i h_\alpha{}^\gamma (\sigma_b)_{\gamma\dot{\alpha}} (\bar{D}^{\dot{\alpha}} \bar{W} - \bar{h}^{\dot{\alpha}\dot{\beta}} \bar{D}_{\dot{\beta} 2} W) + \mathcal{D}_b \Lambda^\alpha \bar{W} \quad (86)$$

$$\mathcal{F}_{ab} = (\sigma_{ab})^{\alpha\beta} h_{\alpha\beta} D_2^2 W - (\tilde{\sigma}_{ab})^{\dot{\alpha}\dot{\beta}} \bar{h}_{\dot{\alpha}\dot{\beta}} \bar{D}_2^2 \bar{W} \quad (87)$$

where all terms are evaluated at $\theta_2 = \Lambda$. We have written the derivatives $D_{\alpha 1}$ in the above expression in terms of $D_{\alpha 2}$ and worldvolume derivatives $\mathcal{D}_\alpha$.

We next impose the standard $\mathcal{F}$ -constraint on this object, i.e. we set $\mathcal{F}_{\alpha\beta} = \mathcal{F}_{ab} = 0$. In terms of ϕ and W_α these constraints are precisely those of the PBGS method [8, 15]

$$0 = \phi + \Lambda^\alpha W_\alpha + \Lambda^2 (1 - \bar{D}^2 \bar{\phi}) - \frac{i}{2} \Lambda^\alpha \bar{\Lambda}^{\dot{\alpha}} \partial_{\alpha \dot{\alpha}} \phi + \frac{i}{2} \Lambda^2 \bar{\Lambda}^{\dot{\alpha}} \partial_{\alpha \dot{\alpha}} W^\alpha - \frac{1}{8} \Lambda^2 \bar{\Lambda}^2 \square \phi \quad (88)$$

$$0 = W_\alpha - \Lambda_\alpha (1 - \bar{D}^2 \bar{\phi}) - i \bar{\Lambda}^{\dot{\alpha}} \partial_{\alpha \dot{\alpha}} \phi - \frac{i}{2} \Lambda_\alpha \bar{\Lambda}^{\dot{\alpha}} \partial_{\beta \dot{\alpha}} W^\beta + \frac{i}{2} \Lambda^\beta \bar{\Lambda}^{\dot{\alpha}} \partial_{\alpha \dot{\alpha}} W_\beta - \frac{1}{4} \Lambda_\alpha \bar{\Lambda}^2 \square \phi + \frac{i}{2} \Lambda^2 \bar{\Lambda}^{\dot{\alpha}} \partial_{\alpha \dot{\alpha}} \bar{D}^2 \bar{\phi} + \frac{1}{8} \Lambda^2 \bar{\Lambda}^2 \square W_\alpha. \quad (89)$$

One can show that $\mathcal{F}_{ab}$ defined this way agrees with (36, 37, 38). We know from (54,55) that on the brane we can replace the constraint (80) with

$$D_2^2 W \Big|_{\theta_2=\Lambda} = -\frac{1 + \bar{k}^2 - \bar{s}^2}{1 - s^2 \bar{s}^2}. \quad (90)$$

Employing the nonlinear reality constraint (39) one finds

$$D_2^2 W \Big|_{\theta_2=\Lambda} = X(h), \quad (91)$$

which gives agreement with the expression for $\mathcal{F}_{ab}$ from the superembedding approach (36, 37, 38).

Again this is as expected because we can use a similar argument to that given in the three dimensional case to show that $\mathcal{F}$ defined by $d\mathcal{F} = -H$ and the $\mathcal{F}$ -constraint is unique.

After a little algebra the constraints (88, 89) imply

$$\phi = \frac{W^2}{1 - \bar{D}\bar{\phi}}. \quad (92)$$

This is the relation first postulated in [8] and later derived algorithmically in [15]. It was shown [8] that it can be used together with its complex conjugate to show that ϕ agrees with a particular form of the $N = 1, D = 4$ supersymmetric Born-Infeld superfield Lagrangian first constructed in [22].

4 Equivalence of the actions

In this section we give a proof that the actions defined via the superembedding method are equivalent to those constructed within the non-linear realisations framework. We construct the Lagrangian form of the superembedding approach in the target space so that it agrees with that constructed in section 2 upon pullback to the worldvolume (i.e. the space defined by $\theta_2 = \Lambda(x, \theta_1)$). We then note that the Lagrangian of the non-linear realisations framework can be obtained from the pullback of the same target space Lagrangian form to the space defined by $\theta_2 = 0$. The two are thus related by an odd diffeomorphism of the target space. Due to the fact that the Lagrangian form is closed we can see that the actions defined by the integrals of the pullbacks are invariant under target space diffeomorphisms and hence the two actions are equal.

4.1 PBGS Action

In [8, 12] it was observed that the leading component of the $N = 2$ Maxwell field W has the correct variation under the non-linear supersymmetry to be a candidate superfield Lagrangian. For the three-dimensional case we can see this in the following way. Recalling that the θ_2 expansion of W is

$$W = \phi + \theta_2^\alpha W_\alpha + \dots \quad (93)$$

we can see that the variation of ϕ under a θ_2 translation with parameter η is

$$\delta_\eta \phi = \eta^\alpha W_\alpha. \quad (94)$$

This implies that $D^2\phi$ varies only by a total derivative

$$\delta_\eta D^2\phi = \eta^\alpha D^2 W_\alpha = \eta^\alpha \partial_{\alpha\beta} W^\beta \quad (95)$$

and hence the action

$$S = \int d^3x D^2\phi \quad \propto \quad \int d^3x d^2\theta \phi \quad (96)$$

is invariant.

Similar relations show the invariance of the the four dimensional action

$$S = \int d^4x (D^2\phi + \bar{D}^2\bar{\phi}) \quad \propto \quad \int d^4x d^2\theta \phi + (\text{c.c.}) \quad (97)$$

Thus in both cases ϕ , the leading component of W , certainly has the correct variation to be a candidate superfield Lagrangian for the space filling brane.

4.2 Target space approach

To show that these actions agree with those defined via the superembedding approach we first construct a target space Lagrangian form. Since we consider space filling branes we employ precisely the same argument that was used to construct the worldvolume Lagrangian forms. We can promote the forms W_{D+1} and Z_D to the target space using the fact that we have defined a modified field strength $\underline{F}$ on the target space:

$$\underline{W}_{D+1} = \underline{G}_{D+1} + \underline{G}_{D-1}\underline{F} \quad (98)$$

$$\underline{Z}_D = \underline{C}_D + \underline{C}_{D-2}\underline{F}. \quad (99)$$

The fact that our branes are space filling means that $\underline{W}_{D+1}$ is a form of degree one higher than the body of the target space. The fact that it is closed therefore implies it is exact and we can find a D -form $\underline{K}_D$ such that $d\underline{K}_D = \underline{W}_{D+1}$. The target space Lagrangian form $\underline{L}_D = \underline{K}_D - \underline{Z}_D$ is then closed by construction.

When performing the superembedding, we consider the map

$$f : \mathcal{M} \longrightarrow \underline{\mathcal{M}}, \quad f : (x, \theta) \longmapsto (x, \theta, \Lambda(x, \theta)). \quad (100)$$

Now we will also want to consider the map

$$i : \mathcal{M} \longrightarrow \underline{\mathcal{M}}, \quad i : (x, \theta) \longmapsto (x, \theta, 0). \quad (101)$$

The pullback of $\underline{L}_D$ to the brane (i.e. $\text{Im } f$) will coincide with the worldvolume Lagrangian form we defined previously (8) in our discussion of the superembedding approach. Also, the top component of the pullback of $\underline{L}_D$ to the space defined by $\theta_2 = 0$ (i.e. $\text{Im } i$) will coincide with the Lagrangian defined via the PBGS method. We will now show this in both cases.

D=3

The non-zero components of the form $\underline{K}_3$ which satisfies $d\underline{K}_3 = \underline{W}_4$ are

$$K_{\underline{abc}} = -i\epsilon_{abc}(D_1^2 W + D_2^2 W) \quad (102)$$

$$K_{\alpha i \underline{bc}} = \epsilon_{bcd}(\gamma^d)_{\alpha\beta} D_i^\beta W \quad (103)$$

$$K_{\alpha i \beta j \underline{c}} = -i(\gamma_c)_{\alpha\beta} \delta_{ij} W \quad (104)$$

We can write the top component as $K_{\underline{abc}} = \epsilon_{abc} \underline{K}$. Using the modified Maxwell relation on W (60) we find

$$\underline{K} = -2iD_2^2 W - 1 = -2iD_1^2 W + 1. \quad (105)$$

Upon pullback to the brane, $\theta_2 = \Lambda$, one can see that only the top component contributes due to the $\mathcal{F}$ -constraint which says $W|_{\theta_2=\Lambda} = 0$ and $D_{\alpha 2} W|_{\theta_2=\Lambda} = 0$. The pullback $f^* \underline{K}_3 = K_3$ therefore has only the abc component. Employing the relation (72) we can see that the only non-zero component of the pullback K_3 is then

$$K_{abc} = \epsilon_{abc} \frac{1 - h^2}{1 + h^2} \quad (106)$$

which agrees with the expression for K_3 derived from the worldvolume approach.

Alternatively we can pull back the form $\underline{L}_3 = \underline{K}_3 - \underline{Z}_3$ to the space defined by $\theta_2 = 0$. We denote this pullback with $i^* \underline{L}_3 = L_3^0$. The top component of L_3^0 is

$$L_{abc}^0 = \epsilon_{abc}(-2iD^2\phi) \quad (107)$$

which agrees with the expression for the PBGS Lagrangian (96).

We can therefore view the target space Lagrangian form as the parent for both actions.

D=4

The non-zero components of the 4-form $\underline{K}_4$ which satisfies $d\underline{K}_4 = \underline{W}_5$ are given by

$$K_{\underline{abcd}} = \frac{1}{2}\epsilon_{abcd}(D_1^2 W + D_2^2 W + \text{c.c}) \quad (108)$$

$$K_{\alpha i \underline{bcd}} = -i\epsilon_{abcd}(\sigma^a)_{\alpha\dot{\alpha}}\bar{D}^{\dot{\alpha}i}\bar{W} \quad (109)$$

$$K_{\alpha i \beta j \underline{cd}} = -2i\delta_{ij}(\sigma_{cd})_{\alpha\beta}\bar{W} \quad (110)$$

We can write the top component as $K_{\underline{abcd}} = \epsilon_{abcd}\underline{K}$. Using the modified Maxwell relation on W for four dimensions (80) we find

$$\underline{K} = D_1^2 W + \bar{D}_1^2 \bar{W} - 1 = D_2^2 W + \bar{D}_2^2 \bar{W} + 1. \quad (111)$$

Pulling back to the brane only the top component contributes due to the $\mathcal{F}$ -constraint. The only non-zero component of the pullback $f^* \underline{K}_4 = K_4$ is the purely bosonic one,

$$K_{abcd} = \epsilon_{abcd}(1 + D_2^2 W + \bar{D}_2^2 \bar{W}) = 1 + X(h) + \bar{X}(h), \quad (112)$$

again giving agreement with the worldvolume approach.

If we pull $\underline{L}_4 = \underline{K}_4 - \underline{Z}_4$ back to $\theta_2 = 0$, defining $L_4^0 = i^* \underline{L}_4$, we find the top component of L_4^0 to be

$$L_{abcd}^0 = \epsilon_{abcd}(D^2\phi + \bar{D}^2\bar{\phi}), \quad (113)$$

giving agreement with the PBGS Lagrangian.

4.3 Proof of equivalence

In both three and four dimensional cases we see that the target space Lagrangian form $\underline{L}$ can be used to describe both the superembedding action and the PBGS action. The PBGS action can be written as

$$\int_{\mathcal{M}_o} e^* i^* \underline{L}, \quad (114)$$

where e^* denotes pullback to the body of $\mathcal{M}$. The superembedding action can be written as

$$\int_{\mathcal{M}_o} e^* f^* \underline{L}. \quad (115)$$

Thus the two actions are integrals of the pullbacks of the closed target space Lagrangian form to different sections of the target space. By section we mean a bosonic submanifold that is diffeomorphic to the body of the supermanifold.

The two integrals are the same by the following argument.

Claim

Consider a supermanifold $\mathcal{M}$ with a D -dimensional body $\mathcal{M}_o$. Consider the two sections e, s of $\mathcal{M}$ defined in each coordinate patch by

$$e : \mathcal{M}_o \mapsto \mathcal{M} \quad ; \quad e : (x^a) \mapsto (x^a, 0). \quad (116)$$

$$s : \mathcal{M}_o \longrightarrow \mathcal{M} \quad ; \quad s : (x^a) \mapsto (x^a, \xi^\alpha(x)). \quad (117)$$

Suppose further that L is a closed D -form on $\mathcal{M}$. Then

$$\int_{\mathcal{M}_o} s^* L = \int_{\mathcal{M}_o} e^* L. \quad (118)$$

This is closely related to the idea of rheonomy in the group manifold approach[23].

Proof

Define the one parameter family of sections s_t (t real) in each patch by

$$s_t : \mathcal{M}_o \longrightarrow \mathcal{M} \quad ; \quad s_t : (x^a) \mapsto (x^a, t\xi^\alpha). \quad (119)$$

In particular $s_0 = e$ and $s_1 = s$.

We also need the one parameter family of diffeomorphisms of $\mathcal{M}$, generated by the odd vector field $\xi = \xi^\alpha D_\alpha$. These are denoted by σ_t and defined in a patch by

$$\sigma_t : \mathcal{M} \longrightarrow \mathcal{M} \quad ; \quad \sigma_t : (x^a, \theta^\alpha) \mapsto (x^a, \theta^\alpha + t\xi^\alpha). \quad (120)$$

We have the composition rule

$$s_{t+r} = \sigma_r \cdot s_t. \quad (121)$$

The claim will be true if

$$S(t) = \int_{\mathcal{M}_o} s_t^* L \quad (122)$$

is independent of t . Differentiating with respect to t , we have

$$\frac{dS}{dt} = \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon} \left(\int_{\mathcal{M}_o} s_{t+\epsilon}^* L - \int_{\mathcal{M}_o} s_t^* L \right) \quad (123)$$

$$= \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon} \int_{\mathcal{M}_o} (s_{t+\epsilon}^* L - s_t^* L) \quad (124)$$

Using the composition rule and the fact that $(f \cdot g)^* = g^* \cdot f^*$, we have

$$\frac{dS}{dt} = \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon} \int_{\mathcal{M}_o} ((\sigma_\epsilon \cdot s_t)^* L - s_t^* L) \quad (125)$$

$$= \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon} \int_{\mathcal{M}_o} (s_t^* \cdot \sigma_\epsilon^* L - s_t^* L) \quad (126)$$

Pulling out the pullback of the section s and taking the limit inside the integral, we then have

$$\frac{dS}{dt} = \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon} \int_{\mathcal{M}_o} s_t^* (\sigma_\epsilon^* L - L) \quad (127)$$

$$= \int_{\mathcal{M}_o} s_t^* \mathcal{L}_\xi L. \quad (128)$$

The Lie derivative $\mathcal{L}_\xi L$ can be written

$$\mathcal{L}_\xi L = di_\xi L + i_\xi dL. \quad (129)$$

Since L is closed this is a total derivative and thus the above integral vanishes. Hence

$$\frac{dS}{dt} = 0. \quad (130)$$

Thus we know that $S(t)$ is constant and hence $S(0) = S(1)$ which proves the claim. Thus the integral of the pullback of a closed D -form is independent of the choice of section.

This claim applied to the case under consideration shows that the superembedding action and PBGS action are the same.

5 Conclusion

In this paper we have discussed the relationship between the superembedding approach to constructing brane worldvolume Lagrangians and the method of using linear and non-linear realisations of partially broken supersymmetry. We have focused in detail on the space filling branes in 3 and 4 dimensions. In particular the starting assumptions of the PBGS method all have a geometrical interpretation in terms of superembeddings. The algebra of derivatives is that induced by the pullback onto the worldvolume of the standard flat target space torsion. We have shown that the introduction of an $N = 2$ Maxwell multiplet satisfying modified constraints can be understood in terms of the D-brane like worldvolume Bianchi identity $d\mathcal{F} = -H$. One introduces an independent target space 2-form $\underline{F}$ which satisfies the corresponding target space identity $d\underline{F} = -\underline{H}$. With the standard Maxwell assumptions about the odd-odd component of this form, this gives the $N = 2$ Maxwell multiplet, with modified constraints in the target space. The covariant non-linear constraints one has to impose in the PBGS approach to get the correct multiplet are none other than the manifestly covariant $\mathcal{F}$ -constraint. With these identifications we have shown that the superfield Lagrangians defined by the superembedding method are precisely equivalent to those invariants constructed via the PBGS method.

It would be interesting to see if the geometrical ideas of representing PBGS outlined here could be used to relate the supersymmetric, non-abelian Born-Infeld action constructed in [24] to a superembedding. This might give some insight into what the correct brane-like form of the non-abelian Born-Infeld action is.

We emphasise that the $N = 2$ Maxwell multiplet in the target space contains no degrees of freedom after imposing the $\mathcal{F}$ -constraint; they are all related to the Goldstone field of the embedding (i.e. the transverse target space fermionic coordinate). Thus it is not clear that one has to have an $N = 2$ Maxwell multiplet in the target space at all. One might be able to take any multiplet described by a 2-form satisfying $d\underline{F} = -\underline{H}$. On pulling this back and imposing the standard $\mathcal{F}$ -constraint on $\mathcal{F} = f^*\underline{F}$ one is guaranteed to have the $N = 1$ Maxwell multiplet on the worldvolume. This may suggest a generalization to, say, the space filling brane in 6 dimensions where an $N = (2, 0)$ Maxwell multiplet does not exist. One might also be tempted to look at branes in curved backgrounds. Recently an action for a membrane in AdS4 was constructed from the non-linear realisations perspective [25].

Appendix : Target space Ramond Potentials

D=3

The $D = 3$ Ramond potentials $\underline{C}_1, \underline{C}_3$ solve the Bianchi identities,

$$\underline{G}_2 = d\underline{C}_1, \quad (131)$$

$$\underline{G}_4 = d\underline{C}_3 - \underline{C}_1 \underline{H}_3. \quad (132)$$

Their non-zero components are : for $\underline{C}_1$,

$$C_{abc} = \epsilon abc \quad (133)$$

$$C_{\alpha 2 bc} = i(\gamma_{bc})\theta^{\beta 2} \quad (134)$$

$$C_{\alpha 1 \beta 1 c} = (\gamma_c)_{\alpha \beta}(\theta^2)^2 \quad (135)$$

$$C_{\alpha 2 \beta 2 c} = -(\gamma_c)_{\alpha \beta}(\theta^2)^2, \quad (136)$$

and for $\underline{C}_3$,

$$C_{\alpha 1} = i\theta_{\alpha}^2. \quad (137)$$

D=4

The $D = 4$ Ramond potentials solve

$$\underline{G}_3 = d\underline{C}_3, \quad (138)$$

$$\underline{G}_5 = d\underline{C}_4 - \underline{C}_2 \underline{H}_3. \quad (139)$$

Their non-zero components are : for $\underline{C}_4$,

$$C_{abcd} = -\epsilon_{abcd} \quad (140)$$

$$C_{\alpha 2 b c d} = -i \epsilon_{b c d e} (\sigma^e)_{\alpha \dot{\beta}} \bar{\theta}_2^{\dot{\beta}} \quad (141)$$

$$C_{\alpha 1 \beta 1 c d} = 2i (\sigma_{cd})_{\alpha \beta} (\bar{\theta}_2)^2 \quad (142)$$

$$C_{\alpha 2 \beta 2 c d} = -2i (\sigma_{cd})_{\alpha \beta} (\bar{\theta}_2)^2, \quad (143)$$

and for $\underline{C}_2$,

$$C_{\alpha 1 b} = (\sigma_b)_{\alpha \dot{\beta}} \bar{\theta}_2^{\dot{\beta}} \quad (144)$$

$$C_{\alpha 1 \beta 2} = i \epsilon_{\alpha \beta} (\bar{\theta}_2)^2, \quad (145)$$

together with those obtained by complex conjugation.
